

TicketSeed

By The Clique at IBM Bob 2.0 Hackathon

Introduction

Paste a client PRD written in plain language. TicketSeed turns it into an ordered sprint plan, then into developer-ready tickets. Every item links back to the client's own words, and gaps become questions to ask them.

Built for small teams, freelancers, and tech leads who start from a client brief.

Problem

Clients send product docs in everyday language. They mix must-haves with wishes and skip data, roles, integrations, and failure cases.

Before any code, someone has to:

- extract the real requirements
- decide what to build first
- split the work into sprints and tickets
- list the questions the document never answers

That work is slow, inconsistent, and the missing questions often show up mid-sprint.

Solution

A web app with two steps:

1. PRD → sprint plan — project summary, requirements, ordered sprints, and client questions.
2. One sprint → tickets — title, description, acceptance criteria, size, priority, and the requirements.

The user reviews and edits in the browser, then exports Markdown or JSON.

What sets it apart: the model proposes, then plain code checks the result. Invented requirements are flagged. Gaps stay as questions. Dependencies cannot form a loop. Oversized (XL) tickets are marked for review.

Tech Stack

- Frontend: React, TypeScript, Vite, Tailwind, react-markdown
- Backend: Python, FastAPI, Pydantic v2
- LLM: Groq, openai/gpt-oss-120b
- Tests: pytest (validators and routes)
- Hosting: Vercel

Stateless backend no database, no accounts. The browser holds the session

Future Plans

- Jira export: create sprints and issues, map size to story points, assign tickets
- Richer input: PDF and Word, not only Markdown
- Saved projects: accounts and history
- Quality: keep tuning prompts so validation warnings stay rare

Team

- **Abdullah Khetran** Backend
- **Tanase Sergiu-Vasile** AI, Prompts, Fixtures, Quality
- **Najmi Hassan** Frontend
- **Muhammad Ali Murtaza** Deployment
